Initial Sensitivity Evaluation of Operational Parameters and Storage Capacities Using the CALFED Post-Processing Operations Model

South of Delta Off-Aqueduct Storage Facilities

OVERVIEW OF EVALAUTION

Introduction

The CALFED Post-Processing Operations Model was developed to evaluate the sensitivity of various operational parameters and physical capacities of potential new storage and conveyance facilities in terms of 1) environmental water supply benefits and 2) urban and agricultural water supply benefits. This relatively simplistic model is suitable for analyzing the effects of various storage operation rules and goals, identifying critical external constraints, and providing initial refinement to the ranges of storage and conveyance capacities to be considered in future studies. Information developed from this evaluation will be used to guide more detailed studies, including DWRSIM system operation studies.

The spreadsheet-based CALFED Post-Processing Operations Model uses the results of DWRSIM benchmark operation studies as input. New storage and conveyance facility operations are simulated assuming surplus water supplies, unused conveyance facility capacities, and unmet urban and agricultural demands as defined by DWRSIM and user-defined environmental demands. While this model provides useful initial information, two important limitations must be considered when interpreting model results. First, the CALFED Post-Processing Operation Model simulations do not integrate the operations of new storage and conveyance components with operation of existing facilities. Second, the model simulations do not dynamically model Delta processes. While these simulations are constrained by surplus Delta water, Delta export limitations, and available physical capacities as defined by DWRSIM, specific in-Delta flows and salinities are not evaluated. Future DWRSIM and Delta hydrodynamic modeling studies must be used to assess the impacts of both of these limitations.

In the evaluation documented in this report, the CALFED Post-Processing Operations Model was used to assess the sensitivity of various operational parameters and storage capacities of south of Delta off-aqueduct storage facilities. After completing sensitivity analyses of individual operational parameters (e.g. level of demand and storage carryover requirements), sets of parameters were chosen for two operation goals. These goals, termed Normal Period Supply Operation and Dry Period Supply Operation in this report, are generally mutually exclusive. Storage operations that target maximum supplies over normal long-term hydrologic periods usually result in limited supplies available in extended dry periods general have a high cost in terms of reduced supplies over normal long-term hydrologic periods.

Because the capacity of Banks Pumping Plant, the State Water Project Delta pumping facility, has a significant affect on potential operation of south of Delta off-aqueduct storage

facilities, two capacities were considered in this evaluation. Under the first condition, existing Banks Pumping Plant capacity is assumed. Under the second condition, an expanded Banks Pumping Plant capacity as proposed in the Department of Water Resources South Delta Improvements Plan is assumed.

Water supply benefits were evaluated for storage capacities ranging from 0 to 3.0 maf for each of the four conditions defined by the two operation goals under two Banks Pumping Plant capacities. The results of this evaluation may be used to appraise relative relationships between benefits and storage capacities; absolute quantities of benefits must be confirmed by more detailed modeling.

Two parallel evaluations were completed for south of Delta off-aqueduct storage facilities dedicated exclusively to 1) environmental water supply benefits and 2) agricultural and urban benefits. These two evaluations are summarized in the following sections of this report. Future evaluations using the CALFED Post-Processing Operations Model will consider the effects of joint storage operations for both environmental water supply benefits and agricultural and urban water supply benefits.

Summary Results

Results of the two parallel evaluations for environmental water supply operations and agricultural and urban water supply operations are summarized in this section. More detailed results are provided in the following sections of this report.

Environmental Water Supply Benefits

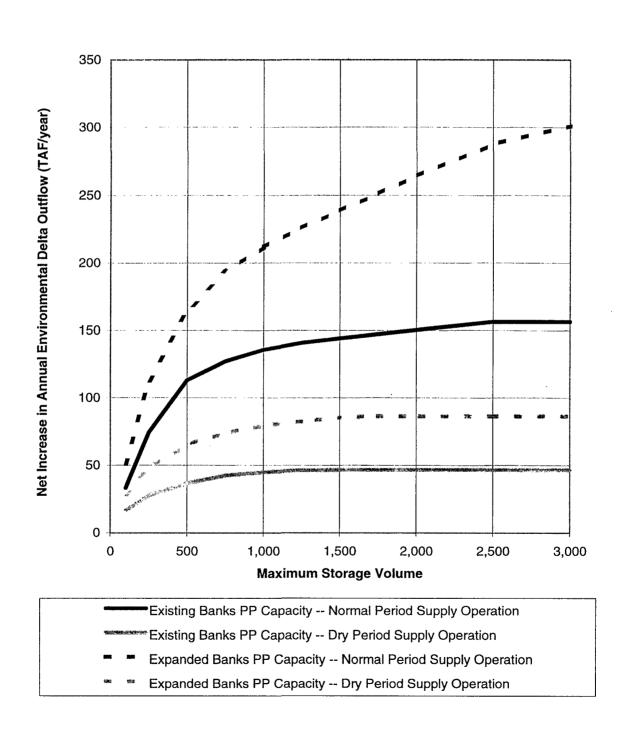

In this evaluation, a minimum Delta outflow target of 12,000 cfs for the months of January through June is used as a surrogate for environmental water demands. Because the CALFED Post-Processing Operations Model uses a monthly time step, more detailed evaluation of flows is not possible with this tool. However, in actual operation, the volume of water released from storage towards the 12,000 cfs target might be used to create higher pulses of flow for shorter durations, if this operation was deemed more environmentally beneficial.

Using this target minimum Delta outflow surrogate approach, environmental water supply benefits are measured in this evaluation by averaging monthly flow rates up to a maximum of 12,000 cfs for January through June of each water year. Any flow above 12,000 cfs is not considered. Note that the result of this computation is significantly lower than and not comparable to *total* average annual Delta outflow. For simplicity in this evaluation, this average of January through June Delta outflows up to 12,000 cfs is termed *Environmental Delta Outflow*.

Summary results of this initial evaluation are presented in Figures 1 and 2. These charts depict net increases in 71-Year Average Annual Environmental Delta Outflow and Minimum Annual Environmental Delta Outflow, respectively, under the four operation conditions described earlier for storage volumes ranging from 0 to 3.0 maf. These two measures of Environmental Delta Outflow reflect Normal Period and Dry Period water supply benefits, respectively.

Expanded Banks PP Capacity -- Normal Period Supply Operation

Expanded Banks PP Capacity -- Dry Period Supply Operation

SE_RVSM.XLS: Net Min Annual Chart

As evidenced by the ranges between the curves of Figures 1 and 2, this initial evaluation demonstrates the importance of operating assumptions on the outcome of water supply evaluations. As expected, normal period supply operations maximize average annual water supplies, but provide little benefit during extended dry periods. On the other hand, dry period supply operations allow for carrying water in storage through extended dry periods, at a very high cost in average annual yield.

This initial evaluation indicates that with existing Banks Pumping Plant capacity only minor environmental water supply benefits might be derived from new south of Delta storage facilities. Potential net benefit in Minimum Annual Environmental Delta Outflow is limited to about 50 taf and is achieved with a maximum storage capacity of 500 taf. The maximum net benefit in 71-Year Average Annual Environmental Delta Outflow with this 500 taf maximum storage capacity is 110 taf. Minor increases in 71-Year Average Annual Environmental Delta Outflow are possible with larger maximum storage capacities.

More significant environmental benefits might be derived from new south of Delta storage facilities with an expanded Banks Pumping Plant capacity. Potential net benefit in Minimum Annual Environmental Delta Outflow could exceed 400 taf with a maximum storage capacity of 1.25 maf. A net benefit in 71-Year Average Annual Environmental Delta Outflow of about 230 taf is possible with this storage capacity. Additional 71-Year Average Annual Delta Outflow could be achieved with additional storage capacity, with a net benefit in 71-Year Average Annual Environmental Delta Outflow of 310 taf with a 3.0 maf storage capacity.

Agricultural and Urban Water Supply Benefits

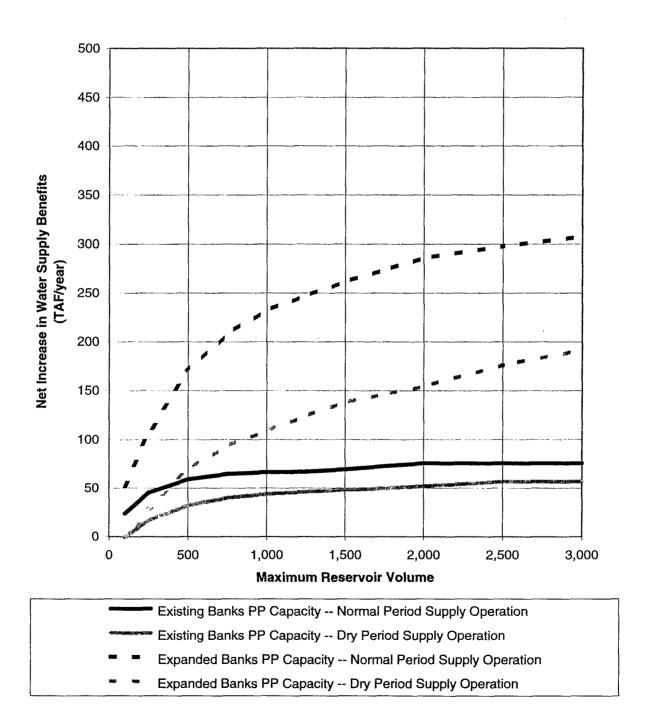

In this evaluation, south of Delta SWP and CVP demands were used as a surrogate for agricultural and urban water supply demands. In actual practice, agricultural and urban water supply benefits from south of Delta storage might be designated to a subset of SWP and CVP users, other south of Delta agricultural and urban users, or upstream of Delta users through a water exchange program.

Summary results of this initial evaluation are presented in Figures 3 and 4. These charts depict net increases in 71-Year Average Annual Agricultural and Urban Water Supply Benefits and Minimum Annual Agricultural and Urban Water Supply Benefits, respectively, under the four operation conditions described earlier for storage volumes ranging from 0 to 3.0 maf. The charts allow comparison of the range of potential benefits under various Banks Pumping Plant capacities, operational goals, and storage capacities.

This initial evaluation indicates that with existing Banks Pumping Plant capacity only minor agricultural and urban water supply benefits might be derived from new south of Delta storage facilities. The net increase in 71-Year Average Annual Agricultural and Urban Water Supply Benefits with a 1.5 maf maximum storage capacity is 70 taf. Only minor increases in 71-Year Average Annual Agricultural and Urban Water Supply Benefits are possible with larger maximum storage capacities. Potential net increase in Minimum Annual Agricultural and Urban Water Supply Benefits is about 250 taf and is achieved with this same maximum storage capacity of 1.5 maf.

SA_RVSM.XLS: Net 71-Yr Avg Chart

Figure 4

South of Delta Off-Aqueduct Storage Net Increase in Minimum Annual Ag & Urban Water Supply Benefits versus Maximum Storage Volume

SA_RVSM.XLS: Net Min Annual Chart

More significant agricultural and urban water supply benefits might be derived from new south of Delta storage facilities with an expanded Banks Pumping Plant capacity. A net increase in 71-Year Average Annual Agricultural and Urban Water Supply Benefits of about 290 taf is possible with a storage capacity of 2.0 maf. Minor additional 71-Year Average Annual Delta Outflow could be achieved with additional storage capacity, with a net benefit of 310 taf with a 3.0 maf storage capacity. Potential net benefit in Minimum Annual Agricultural and Urban Water Supply Benefits could exceed 420 taf with a maximum storage capacity of 2.0 maf.

Initial Sensitivity Evaluation of Operational Parameters and Storage Capacities Using the CALFED Post-Processing Operations Model

South of Delta Off-Aqueduct Storage Facilities

ENVIRONMENTAL WATER SUPPLY EVALUATION

Introduction

Environmental water supply benefits from new south of Delta storage facilities would be achieved by instituting an exchange with south of Delta agricultural and urban water users. Under this arrangement, water would be released from new storage facilities to meet existing downstream agricultural and urban water supply needs. In return, agricultural and urban water users would forego a like amount of exports at the Delta. The capacity of the new storage facility, rules governing diversions into storage, and operational goals (e.g. maximum normal period supply or maximum dry period supply) all affect the magnitude of potential environmental water supply benefits.

The CALFED spreadsheet operations model was used to evaluate effects of various operational rules and physical capacities of new south of Delta storage facilities on potential environmental water supply benefits. A sensitivity analysis was conducted by individually exercising the operational parameters through reasonable ranges with a set south of Delta maximum storage capacity of 2.0 maf and inflow/outflow conveyance capacities of 3,500 cfs, devoted exclusively to environmental water supply. Information from this phase of the evaluation was then used to develop four sets of parameters which collectively bracket the range of potential operations. These four sets of parameters define two operational goals implemented under two external conditions.

The first operational goal modeled is to maximize supplies over normal hydrologic periods. This goal is achieved by imposing no storage carryover requirement and releasing water from storage whenever unmet demand exists. A by-product of this type of operation is that supplies in storage are often depleted when entering critically dry periods. The second operational goal is to maximize supplies in the driest years of normal hydrologic sequences. This goal is achieved by imposing carryover requirements or limiting the amount of water delivered from storage in any given year. While this type of operation usually results in relatively larger quantities of water in storage for use during extended dry periods, overall long-term water deliveries are diminished.

The two external conditions considered in this evaluation address the capacity of Banks Pumping Plant, the State Water Project Delta pumping facility. Capacity of Banks Pumping Plant significantly affects storage operations under both the normal period supply and dry period supply operational goals considered in this evaluation. Under the first external condition, existing Banks Pumping Plant capacity is assumed. Under the

Table SE-1
Bracketing Operational Conditions

Condition	Description
А	Existing Banks PP Capacity Normal Period Supply Operation. This condition assumes that diversions to south of Delta storage are limited by existing Banks Pumping Plant capacity and that the storage facility is operated to provide maximum supplies over normal hydrologic periods.
В	Existing Banks PP Capacity Dry Period Supply Operation. This condition assumes that diversions to south of Delta storage are limited by existing Banks Pumping Plant capacity and that the storage facility is operated to provide maximum supplies in critically dry years.
С	Expanded Banks PP Capacity Normal Period Supply Operation. This condition assumes that diversions to south of Delta storage are supplemented by an increased Banks Pumping Plant capacity as proposed in the Department of Water Resources Interim South Delta Improvement Plan and that the storage facility is operated to provide maximum supplies over normal hydrologic periods.
D	Expanded Banks PP Capacity Dry Period Supply Operation. This condition assumes that diversions to south of Delta storage are supplemented by an increased Banks Pumping Plant capacity as proposed in the Department of Water Resources Interim South Delta Improvement Plan and that the storage facility is operated to provide maximum supplies in critically dry years.

Table SE-2
Statistical Measures of Environmental Delta Outflow

Measure	Description
1	71-Year Average Annual Environmental Delta Outflow. Annual average over the historical hydrologic sequence used in the model simulations.
2	1928-34 Critical Dry Period Average Annual Environmental Delta Outflow. Annual average over the seven year critical dry period.
3	Average Dry Year Environmental Delta Outflow. Annual average over the sixteen water years classified as dry years within the 71-year hydrologic sequence.
4	Average Critically Dry Year Environmental Delta Outflow. Annual average over the eleven water years classified as critically dry years within the 71-year hydrologic sequence.
5	Minimum Annual Environmental Delta Outflow. The minimum annual quantity that occurs over the 71-year hydrologic sequence.

second external condition, an expanded Banks Pumping Plant capacity as proposed in the Department of Water Resources South Delta Improvements Plan is assumed. The four operation conditions defined by the two operational goals under these two external conditions are described in Table SE-1.

Once developed, parameters sets for each of the four operation conditions were input to the CALFED spreadsheet operations model. Potential environmental water supply benefits were evaluated for maximum storage capacities ranging from 100 taf to 3.0 maf. In this evaluation, a minimum Delta outflow target of 12,000 cfs for the months of January through June is used as a surrogate for environmental water demands. Because the CALFED spreadsheet operations model uses a monthly time step, more detailed evaluation of flows is not possible with this tool. However, in actual operation, the volume of water released from storage towards the 12,000 cfs target might be used to create higher pulses of flow for shorter durations, if this operation was deemed more environmentally beneficial.

Using this target minimum Delta outflow surrogate approach, environmental water supply benefits are measured in this evaluation by averaging monthly flow rates up to a maximum of 12,000 cfs for January through June of each water year. Any flow above 12,000 cfs is not considered. Note that the result of this computation is significantly lower than and not comparable to *total* average annual Delta outflow. For simplicity in this evaluation, this average of January through June Delta outflows up to 12,000 cfs is termed *Environmental Delta Outflow*. Five statistical measures of Environmental Delta Outflow are included in this analysis, as described in Table SE-2.

Environmental water supply benefits, as described by these five measures, were estimated for each of the four sets of operation conditions over the range of maximum storage volumes. While this information should not be considered definitive, this evaluation illustrates the potential for environmental benefits from south of Delta storage facilities and the effects of various operation conditions. The information developed in this evaluation may be used to provide an initial refinement of the range of storage volumes of potential south of Delta storage facilities which should be considered in future studies.

Summary

This evaluation provides initial quantitative information on environmental water supply benefits that might be provided by new south of Delta storage facilities. Additional information on water quality benefits, interaction with agricultural and urban water supply opportunities, interactions with other potential new storage and conveyance facilities, costs of new storage facilities, and environmental acceptability of new storage facilities must all be considered in a further refinement of environmental water storage facilities.

Summary results of this initial evaluation are presented in Figures SE-1 and SE-2. These charts depict net increases in 71-Year Average Annual Environmental Delta Outflow and Minimum Annual Environmental Delta Outflow, respectively, under the four operation conditions described in Table SE-1 for storage volumes ranging from 0 to 3.0 maf. The charts allow comparison of the range of potential benefits under various Banks Pumping Plant capacities, operational goals, and storage capacities.

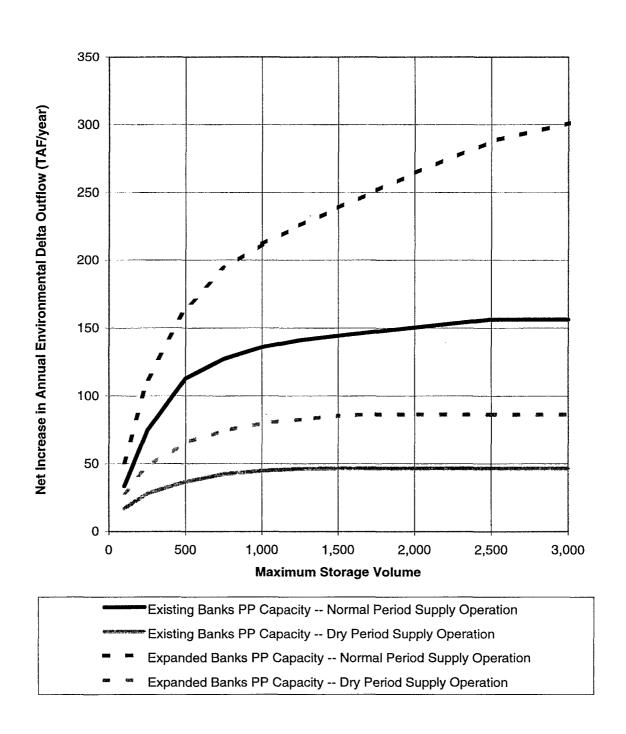

As evidenced by the ranges between the curves of Figures SE-1 and SE-2, this initial evaluation demonstrates the importance of operating assumptions on the outcome of water supply evaluations. As expected, normal period supply operations maximize average annual water supplies, but provide little benefit during extended dry periods. On the other hand, dry period supply operations allow for carrying water in storage through extended dry periods, at a very high cost in average annual yield. This is most vividly illustrated by comparing the curves representing Existing Banks Pumping Plant Capacity -- Dry Period Supply Operation in Figures SE-1 and SE-2. In both figures, at a storage volume of 1.0 maf the Existing Banks Pumping Plant Capacity -- Dry Period Supply Operation reaches an asymptotic net increase of about 50 taf. However, with the same 1.0 maf storage capacity, the Existing Banks Pumping Plant Capacity -- Normal Period Supply Operation yields a net increase of about 140 taf in the 71-Year Average Annual Environmental Delta Outflow compared to a 0 taf net increase for the Minimum Annual Environmental Delta Outflow.

This initial evaluation indicates that with existing Banks Pumping Plant capacity only minor environmental water supply benefits might be derived from new south of Delta storage facilities. Potential net benefit in Minimum Annual Environmental Delta Outflow is limited to about 50 taf and is achieved with a maximum storage capacity of 500 taf. The maximum net benefit in 71-Year Average Annual Environmental Delta Outflow with this 500 taf maximum storage capacity is 110 taf. Minor increases in 71-Year Average Annual Environmental Delta Outflow are possible with larger maximum storage capacities.

More significant environmental benefits might be derived from new south of Delta storage facilities with an expanded Banks Pumping Plant capacity. Potential net benefit in Minimum Annual Environmental Delta Outflow could exceed 400 taf with a maximum storage capacity of 1.25 maf. A net benefit in 71-Year Average Annual Environmental Delta Outflow of about 230 taf is possible with this storage capacity. Additional 71-Year Average Annual Delta Outflow could be achieved with additional storage capacity, with a net benefit in 71-Year Average Annual Environmental Delta Outflow of 310 taf with a 3.0 maf storage capacity.

Environmental Water Supply Benefits versus Storage Carryover Factor Background

The storage carryover factor is an operational parameter designed to provide a means of reserving water supplies for use throughout extended dry periods. In practice, complex reservoir storage carryover rules may be devised to take into account runoff forecasting, variable demand, current storage volume, and other criteria. In this model, a simple storage carryover function has been included which allows the user to set a fraction of end-of-September storage from the previous water year that will be required to remain in storage at the end of the current water year. For example, if 100 taf are in storage at the end of September of the current year, with a storage carryover factor of 70 percent, the storage facility must maintain at least 70 taf by the end of September of the following year. While implementing conservative carryover rules in reservoir operations will increase available supplies during dry periods, total deliveries over normal hydrologic periods will be reduced in comparison to more aggressive reservoir operations.

Model Runs

Storage carryover factors ranging from 0 to 70 percent were varied in a set of model runs to evaluate effects on water supply benefits 1) with and without expanded Banks Pumping Plant capacity, 2) with varied targets for minimum Delta outflow, and 3) with varied unmet demand target factors (described below). These model runs are described in Table SE-3 and summary results are displayed in Table SE-4. For comparability, all results are measured using the Environmental Delta Outflow criteria (average of January through June monthly Delta outflows up to 12,000 cfs) described previously.

Evaluation -- Sensitivity Analysis

Varying the storage carryover factor results in negligible effects for all runs with existing Banks Pumping Plant capacity. Less than 1-percent differences are seen in 71-year average and minimum annual Environmental Delta Outflow throughout the range of storage carryover factors evaluated. Charts displaying the five measures of Environmental Delta Outflow described in Table SE-2 plotted versus storage carryover factor for the existing Banks Pumping Plant capacity condition are shown in Figures SE-3 through SE-6.

Minor effects occur in runs with expanded Banks Pumping Plant capacity. Less than 1-percent decreases in 71-Year Average Annual Environmental Delta Outflow and a maximum 5-percent increase in Minimum Annual Environmental Delta Outflow are seen while varying storage carryover factors between 0 percent and 70 percent. A 7-percent decrease occurs in Minimum Annual Environmental Delta Outflow while increasing the storage carryover factor from 0 to 70 percent, with Delta outflow target set at 9,000 cfs and unmet demand factor set at 50 percent. Plots of the five measures of Environmental Delta Outflow versus storage carryover factor for the expanded Banks Pumping Plant capacity condition are shown in Figures SE-7 through SE-10.

The storage carryover factor has a minimal effect in reserving water supplies through extended dry periods when there are high levels of environmental demand in comparison to potential reservoir yield. The largest effects are produced when target Delta outflow is reduced.

Water Supply Benefits versus January - June Delta Outflow Target Background

A minimum Delta outflow target for the months of January through June is used in this evaluation as a surrogate for environmental water demands. Higher demand levels (higher Delta outflow targets) deplete reservoir storage more often, resulting in higher average deliveries over normal hydrologic periods but reduced deliveries during extended dry periods.

Model Runs

Minimum Delta outflow targets ranging from 8,000 to 15,000 cfs were varied in a set of model runs to evaluate effects on water supply benefits 1) with and without expanded Banks Pumping Plant capacity, 2) varied storage carryover factors, and 3) varied unmet demand target factors (described below). These model runs are described in Table SE-5 and summary results are displayed in Table SE-6. For comparability, all results are measured using the Environmental Delta Outflow criteria (average of January through June monthly Delta outflows up to 12,000 cfs) described previously.

Evaluation -- Sensitivity Analysis

Minor effects of varying minimum Delta outflow targets are observed in runs with existing Banks Pumping Plant capacity. Less than a 3-percent increase in 71-Year Average Annual Environmental Delta Outflow and less than a 2-percent decrease in Minimum Annual Environmental Delta Outflow are observed as the operating target is increased from 8,000 to 15,000 cfs. Variable effects are seen in dry and critical year averages, all within a 7-percent range. Plots of the five measures of Environmental Delta Outflow versus January - June Delta outflow target for the existing Banks Pumping Plant capacity condition are shown in Figures SE-11 through SE-14.

Significant effects are observed in runs with expanded Banks Pumping Plant capacity. Increases of 4 to 5 percent occur in 71-year averages. Increases of up to 17 percent in Minimum Annual Environmental Delta Outflow result as the operating target is reduced from 12,000 cfs to 9,000, with storage carryover factor set at 0 percent and unmet demand factor (see next section) set at 50 percent. Plots of the five measures of Environmental Delta Outflow versus January - June Delta outflow target for the expanded Banks Pumping Plant condition are shown in Figures SE-15 through SE-18.

This operational parameter has a significant effect on minimum annual benefits with increased Banks Pumping Plant capacity in place. A target of 9,000 cfs produces the highest minimum annual benefits with minor losses in average annual benefits.

SE_DE8.XLS: XY-Tot Chart 1

Environmental Water Supply Benefits versus Unmet Demand Target Factor Background

Because the storage carryover factor as implemented in the CALFED spreadsheet operations model was only minimally effective in reserving water supplies for the most critically dry years, an additional operational parameter, the unmet demand target factor, was developed and added to the model. The unmet demand target factor limits the amount of release from water supply in any month to a set percentage of the unmet demand. With this factor set at 100 percent, releases are made from storage to meet any shortage in Delta outflow in comparison to the Delta outflow target. With the factor set at 50 percent, releases are made from storage to meet only half of the shortage in Delta outflow. Because unmet demand during extended dry periods overwhelms potential storage facility yield, implementing this parameter at levels below 100 percent limits releases from storage, providing additional supplies in later stages of extended dry periods.

Model Runs

Unmet demand target factors ranging from 30 percent to 100 percent were varied in a set of model runs to evaluate effects on water supply benefits 1) with and without expanded Banks Pumping Plant capacity, 2) varied storage carryover factors, and 3) varied Delta outflow targets. These model runs are described in Table SE-7 and summary results are displayed in Table SE-8. For comparability, all results are measured using the Environmental Delta Outflow criteria (average of January through June monthly Delta outflows up to 12,000 cfs) described previously.

Evaluation -- Sensitivity Analysis

Minor effects were exhibited in model runs with existing Banks Pumping Plant capacity. Less than 2-percent increases in 71-Year Annual Average Environmental Delta Outflow and less than 2-percent decreases in Minimum Annual Environmental Delta Outflow occur as the unmet demand target factor is increased from 30 percent to 100 percent. Maximum increases in Minimum Annual Environmental Delta Outflow occur with the unmet demand factor set at 30 percent. Variable effects occur in dry and critical year averages, all within a 4-percent range. Plots of the five measures of Environmental Delta Outflow versus unmet demand target factor for the existing Banks Pumping Plant capacity condition are shown in Figures SE-19 through SE-22.

More significant effects occur in model runs with expanded Banks Pumping Plant capacity and storage carryover factor set at 0 percent. Along with minor increases of 2 to 3 percent in 71-year Average Annual Environmental Delta Outflow, substantial increases of up to 12 percent in Minimum Annual Environmental Delta Outflow occur with the Delta outflow target set at 12,000 cfs and the storage carryover factor set at 0 percent. With the Delta outflow target set at 9,000 cfs, the storage carryover factor set at 0 percent, and the unmet demand factor set at 50 percent, maximum increases of up to 12 percent in Minimum Annual Environmental Delta Outflow occur. This combination of operation parameters results in the highest Minimum Annual Environmental Delta Outflow of any combination of operational parameters evaluated. Plots of the five measures of Environmental Delta Outflow versus unmet demand target factor for the expanded Banks Pumping Plant capacity condition are shown in Figures SE-23 through SE-26.

The environmental water supply demands considered in this evaluation significantly outweigh potential south of Delta reservoir yields. As a result, the storage carryover factor operational criteria is ineffective in reserving water supplies through extended dry periods. Application of an unmet demand factor of less than 100 percent has the effect of emphasizing deliveries in drier years. This operational control is more effective in maximizing Environmental Delta Outflow in the last years of critical dry periods than the storage carryover factor.

The combination of Delta outflow target set at 9,000 cfs, the storage carryover factor set at 0 percent, and the unmet demand factor set at 50 percent results in the highest Minimum Annual Environmental Delta Outflow of any combination of operational parameters evaluated. However, water supply benefits over normal hydrologic periods are diminished in inverse proportion as critical period supplies are emphasized.

Selection of Bracketing Operational Parameter Sets

As described in the previous sections, sensitivity analyses were conducted using the CALFED spreadsheet operations model to identify the effects of various operational parameters on environmental water supply benefits. Using the information developed through this process, parameter sets were selected to represent the four bracketing operation conditions described in Table SE-1.

Parameter sets which maximized 71-year Average Annual Environmental Delta Outflow were chosen for the Normal Period Supply Operation conditions. Emphasizing this long-term average clearly results in the largest quantity of total water supply deliveries over the 71-year hydrologic period. Developing a rational for selecting parameter sets for Dry Period Supply Operation conditions is more complex. Several sets of operational parameters resulted in relatively large Average Dry Year, Average Critically Dry Year, or 1928-34 Critical Dry Period Average Annual Environmental Delta Outflows. When examined in detail, however, it was found the large averages are often due to a particularly large storage release in one or two years, while no benefits are provided during many other critical years. Because of this, parameter sets which maximized Minimum Annual Environmental Delta Outflow were selected for the Dry Period Supply Operation conditions.

Parameter sets for Normal Period Supply Operation and Dry Period Supply Operation were selected for the two external conditions considered in this evaluation, existing Banks Pumping Plant capacity and expanded Banks Pumping Plant capacity. The resulting parameter sets for each of the four bracketing operation conditions are detailed in Table SE-9.

√ Table SE-9

South of Delta Off-Aqueduct Storage Selected Parameter Sets for Bracketing Operational Conditons

Operational Condition	Parameter Sets
A. Existing Banks PP Capacity Normal Period Supply Operation	Existing Banks PP Capacity Storage Carryover Factor = 0% Unmet Demand Target Factor = 100% Jan-Jun Outflow Target = 15,000 cfs
B. Existing Banks PP Capacity Dry Period Supply Operation	Existing Banks PP Capacity Storage Carryover Factor = 50% Unmet Demand Target Factor = 30% Jan-Jun Outflow Target = 9,000 cfs
C. Expanded Banks PP Capacity Normal Period Supply Operation	SDI Banks PP Capacity Storage Carryover Factor = 0% Unmet Demand Target Factor = 100% Jan-Jun Outflow Target = 15,000 cfs
D. Expanded Banks PP Capacity Dry Period Supply Operation	SDI Banks PP Capacity Storage Carryover Factor = 0% Unmet Demand Target Factor = 50% Jan-Jun Outflow Target = 9,000 cfs

Comparison of Bracketing Operation Conditions

Model Runs

Model runs were completed for each of the four operation conditions using the parameter sets described in Table SE-9. For comparative purposes, maximum storage volume was set at 2.0 maf with a 3,500 cfs inflow/outflow capacity. Table SE-10 compares the total and net increased Environmental Delta Outflow under each operation condition.

Evaluation

The Normal Period Supply and Dry period Supply Operation conditions bracket the range of potential storage operations. Normal Period Supply Operation maximizes total average water supply benefits, as measured by the 71-Year Average Annual Environmental Delta Outflow. Dry Period Supply Operation maximizes water supply benefits in extremely dry years, as measured by the Minimum Annual Environmental Delta Outflow. Contrasting these bracketing operations for the existing Banks Pumping Plant capacity condition, Normal Period Supply Operation (Condition A) results in a net benefit of 150 taf in 71-Year Average Annual Environmental Delta Outflow, as compared to a net benefit of 50 taf under Dry Period Supply Operation (Condition B). Conversely, Dry Period Supply Operation (Condition B) results in a net benefit of 50 taf in Minimum Annual Environmental Delta Outflow under Normal Period Supply Operation (Condition A).

More significant benefits are achieved under the expanded Banks Pumping Plant capacity conditions. Contrasting the bracketing Operation Conditions C and D, Normal period Supply Operation (Condition C) results in a net benefit of 270 taf in 71-Year Average Annual Environmental Delta Outflow, as compared to a net benefit of 90 taf under Dry Period Supply Operation (Condition D). Conversely, Dry Period Supply Operation results in a net benefit of 50 taf in Minimum Annual Environmental Delta Outflow, compared to a net benefit of 0 taf in Minimum Annual Environmental Delta Outflow under Normal Period Supply Operation.

Figures SE-27 and SE-28 compare the relative effects of the four operation conditions on an annual basis. In these charts, bars represent the total Environmental Delta Outflow for the 71 years used in the model simulations, sorted from minimum to maximum. For comparison, base case Environmental Delta Outflow is represented with a line in each chart. Figure SE-27 compares Normal Period Supply and Dry Period Supply Operations (Conditions A & B) for the existing Banks Pumping Plant capacity condition. While minor benefits are seen during the driest years under Dry Period Supply Operation (Condition B), benefits during average-type water years is significantly reduced. Similarly, Figure SE-28 compares Normal Period Supply and Dry Period Supply Operations (Conditions C & D) for the expanded Banks Pumping Plant capacity condition. More significant benefits occur during the very driest years under Dry Period Supply Operation (Condition D); however, benefits during average-type water years are once again significantly reduced in comparison to Normal Period Supply Operation (Condition C).

Figure SE-29 presents the same data used in Figures SE-27 and SE-28 in a frequency-of-exceedence format. In this chart, total annual Environmental Delta Outflow for the base case and the four operation conditions is plotted against frequency of exceedence. As

described above, significantly higher benefits in average-type years are shown with Normal Period Supply Operation, with relatively smaller net gains in drier years under Dry Period Supply Operation.

To provide a better understanding of the year-to-year operations that occur under the four bracketing operation conditions, Figures SE-30 through SE-33 display the simulated storage releases that occur throughout the 71-year hydrological sequence. In each chart, bars represent annual volumes of storage releases and a solid line represents the annual volume of water required to fully meet the Environmental Delta Outflow target of 12,000 cfs for January through June. For each operation condition, an operational Delta outflow target was chosen to control storage operations. A dashed line represents the annual volume of water required to meet this operational Delta outflow target. As can be seen in these charts, under Normal Period Supply Operations (Conditions A and C) larger annual volumes of water are released in relatively few years of the 71-year hydrologic sequence. Under Dry Period Supply Operations (Conditions B and D), annual releases are much smaller, but occur on a much more frequent basis.

Simulated end-of-month storage volumes for the four bracketing operation conditions are shown in Figures SE-34 through SE-37. As expected, storage volumes show much larger variability under Normal Period Supply Operations (Conditions A and C) in comparison to Dry Period Supply Operations (Conditions B and D). Under Condition A (Existing Banks Pumping Plant -- Normal Period Supply Operation), the maximum storage volume of 2.0 maf is reached in only one year of the 71-year hydrologic sequence. Contrarily, under Condition D (Expanded Banks Pumping Plant Capacity -- Dry Period Supply Operation), the 2.0 maf storage volume remains mostly full over much of the 71-year hydrologic sequence.

Unmet Demand Target Factor = 50%

Water Supply Benefits versus Maximum Storage Volume Model Runs

Maximum storage volumes ranging from 100 taf to 2.0 maf were varied in a set of model runs that simulated the four bracketing operation conditions described previously. These model runs are described in Table SE-11 and summary results are displayed in Tables SE-12 and SE-13. For comparability, all results are measured using the Environmental Delta Outflow criteria (average of January through June monthly Delta outflows up to 12,000 cfs) described previously.

Evaluation

Table SE-12 displays the five statistical measures of total Environmental Delta Outflow achieved over the range of maximum storage volumes studied for each of the bracketing operation conditions. Table SE-13 displays net increases in Environmental Delta Outflow for the same range of maximum storage volumes and operation conditions. Figures SE-38 through SE-42 display plots of total Environmental Delta Outflow versus maximum storage volumes. Figures SE-43 through SE-47 display plots of net increases in Environmental Delta Outflow. The wide range of benefits seen in these plots between operation conditions for any given maximum reservoir volume confirms that operation conditions must be more thoroughly defined before the maximum storage volume of south of Delta storage facilities can be optimized.

Figures SE-38 and SE-43 show that maximum 71-Year Average Annual Environmental Delta outflow is achieved under Condition C (Expanded Banks Pumping Plant Capacity -- Normal Period Supply Operation). Under this operating condition, 71-Year Average Annual Environmental Delta Outflow continues to increase with diminishing incremental benefit throughout the range of maximum storage volumes evaluated. With a maximum storage volume of 3.0 maf, the largest maximum storage volume evaluated, a net increase of 310 taf is observed in 71-Year Average Annual Environmental Delta Outflow. About 71 percent of this net benefit, a 220 taf increase in 71-Year Average Annual Environmental Delta Outflow, is achieved with a maximum storage volume of only 1.0 maf.

Under Condition A (Existing Banks Pumping Plant Capacity -- Normal Period Supply Operation), 71-Year Average Annual Environmental Delta Outflow also increases throughout the range of maximum storage volumes evaluated, but with much smaller incremental gains in comparison to Condition C. With a maximum storage volume of 3.0 maf, a net increase of 160 taf occurs in the 71-Year Average Annual Environmental Delta Outflow. About 72 percent of this net benefit, or 110 taf is achieved with a 500 taf maximum storage volume.

Figures SE-42 and SE-47 indicate that the largest Minimum Annual Environmental Delta Outflow is achieved under Condition D (Expanded Banks Pumping Plant Capacity -- Dry Period Supply Operation). Under this operating condition, Minimum Annual Environmental Delta Outflow increases dramatically between maximum storage volumes of 500 taf and 1.0 maf. A maximum net benefit of 400 taf in Minimum Annual Environmental Delta Outflow is observed with a maximum storage volume of 1.25 maf. Under Condition D, no additional Minimum Annual Environmental Delta Outflow is achieved with maximum storage volumes larger than 1.25 maf.

Under Condition B (Existing Banks Pumping Plant Capacity -- Dry Period Supply Operation), a net increase in Minimum Annual Environmental Delta Outflow of 50 taf is observed with a maximum storage volume of 500 taf. Under Condition B, no significant additional Environmental Delta Outflow benefits are achieved with maximum storage volumes larger than 500 taf.

Initial Sensitivity Evaluation of Operational Parameters and Storage Capacities Using the CALFED Post-Processing Operations Model

South of Delta Off-Aqueduct Storage Facilities

AGRICULTURAL AND URBAN WATER SUPPLY EVALUATION

Introduction

Agricultural and urban water supply benefits from new south of Delta storage facilities would be achieved by diverting Delta water for storage during times of high flows and concurrent low-impacts to the Delta ecosystem. This stored water would be released for use during periods of need. The capacity of the new storage facility, rules governing diversions into storage, and operational goals (e.g. maximum normal period supply or maximum dry period supply) all affect the magnitude of potential agricultural and urban water supply benefits.

The CALFED spreadsheet operations model was used to evaluate effects of various operational rules and physical capacities of new south of Delta storage facilities on potential agricultural and urban water supply benefits. A sensitivity analysis was conducted by individually exercising the operational parameters through reasonable ranges with a set south of Delta maximum storage capacity of 2.0 maf and inflow/outflow conveyance capacities of 3,500 cfs, devoted exclusively to agricultural and urban water supply. Information from this phase of the evaluation was then used to develop four sets of parameters which collectively bracket the range of potential operations. These four sets of parameters define two operational goals implemented under two external conditions.

The first operational goal modeled is to maximize supplies over normal hyrdrologic periods. This goal is achieved by imposing no storage carryover requirement and releasing water from storage whenever unmet demand exists. A by-product of this type of operation is that supplies in storage are often depleted when entering critically dry periods. The second operational goal is to maximize supplies in the driest years of normal hydrologic sequences. This goal is achieved by imposing carryover requirements or limiting the amount of water delivered from storage in any given year. While this type of operation usually results in relatively larger quantities of water in storage for use during extended dry periods, overall long-term water deliveries are diminished.

The two external conditions considered in this evaluation address the capacity of Banks Pumping Plant, the State Water Project Delta pumping facility. Capacity of Banks Pumping Plant significantly affects storage operations under both the normal period supply and dry period supply operational goals considered in this evaluation. Under the first external condition, existing Banks Pumping Plant capacity is assumed. Under the

Table SA-1
Bracketing Operational Conditions

Condition	Description
А	Existing Banks PP Capacity Normal Period Supply Operation. This condition assumes that diversions to south of Delta storage are limited by existing Banks Pumping Plant capacity and that the storage facility is operated to provide maximum supplies over normal hydrologic periods.
В	Existing Banks PP Capacity Dry Period Supply Operation. This condition assumes that diversions to south of Delta storage are limited by existing Banks Pumping Plant capacity and that the storage facility is operated to provide maximum supplies in critically dry years.
С	Expanded Banks PP Capacity Normal Period Supply Operation. This condition assumes that diversions to south of Delta storage are supplemented by an increased Banks Pumping Plant capacity as proposed in the Department of Water Resources Interim South Delta Improvement Plan and that the storage facility is operated to provide maximum supplies over normal hydrologic periods.
D	Expanded Banks PP Capacity Dry Period Supply Operation. This condition assumes that diversions to south of Delta storage are supplemented by an increased Banks Pumping Plant capacity as proposed in the Department of Water Resources Interim South Delta Improvement Plan and that the storage facility is operated to provide maximum supplies in critically dry years.

Table SA-2
Statistical Measures of Agricultural and Urban Water Supply Benefits

Measure	Description
1	71-Year Average Annual Agricultural and Urban Water Supply Benefits. Annual average over the historical hydrologic sequence used in the model simulations.
2	1928-34 Critical Dry Period Average Annual Agricultural and Urban Water Supply Benefits. Annual average over the seven year critical dry period.
3	Average Dry Year Agricultural and Urban Water Supply Benefits. Annual average over the sixteen water years classified as dry years within the 71-year hydrologic sequence.
4	Average Critically Dry Year Agricultural and Urban Water Supply Benefits. Annual average over the eleven water years classified as critically dry years within the 71-year hydrologic sequence.
5	Minimum Annual Agricultural and Urban Water Supply Benefits. The minimum annual quantity that occurs over the 71-year hydrologic sequence.

second external condition, an expanded Banks Pumping Plant capacity as proposed in the Department of Water Resources South Delta Improvements Plan is assumed. The four operation conditions defined by the two operational goals under these two external conditions are described in Table SA-1.

Once developed, parameters sets for each of the four operation conditions were input to the CALFED spreadsheet operations model. Potential agricultural and urban water supply benefits were evaluated for maximum storage capacities ranging from 100 taf to 3.0 maf. In this evaluation, south of Delta SWP and CVP demands were used as a surrogate for agricultural and urban water supply demands. In actual practice, agricultural and urban water supply benefits from south of Delta storage might be designated to a subset of SWP and CVP users, other south of Delta agricultural and urban users, or upstream of Delta users through a water exchange program. Five statistical measures of agricultural and urban water supply benefits are included in this analysis, as described in Table SA-2.

Agricultural and urban water supply benefits, as described by these five measures, were estimated for each of the four sets of operation conditions over the range of maximum storage volumes. While this information should not be considered definitive, this evaluation illustrates the potential for agricultural and urban benefits from south of Delta storage facilities and the effects of various operation conditions. The information developed in this evaluation may be used to provide an initial refinement of the range of storage volumes of potential south of Delta storage facilities which should be considered in future studies.

Summary

This evaluation provides initial quantitative information on agricultural and urban water supply benefits that might be provided by new south of Delta storage facilities. Additional information on water quality benefits, interaction with environmental water supply opportunities, interactions with other potential new storage and conveyance facilities, costs of new storage facilities, and environmental acceptability of new storage facilities must all be considered in a further refinement of agricultural and urban water storage facilities.

Summary results of this initial evaluation are presented in Figures SA-1 and SA-2. These charts depict net increases in 71-Year Average Annual Agricultural and Urban Water Supply Benefits and Minimum Annual Agricultural and Urban Water Supply Benefits, respectively, under the four operation conditions described in Table SA-1 for storage volumes ranging from 0 to 3.0 maf. The charts allow comparison of the range of potential benefits under various Banks Pumping Plant capacities, operational goals, and storage capacities.

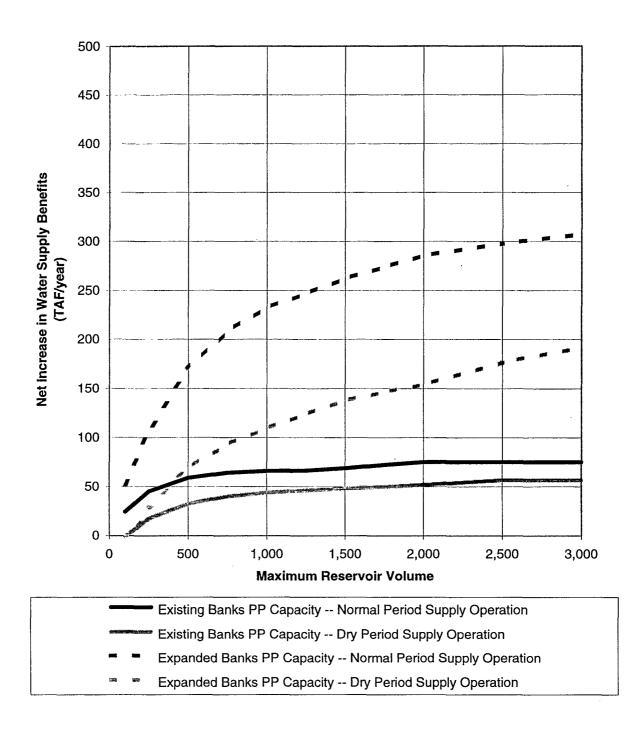

As evidenced by the ranges between the curves of Figures SA-1 and SA-2, this initial evaluation demonstrates the importance of operating assumptions on the outcome of water supply evaluations. As expected, normal period supply operations maximize average annual water supplies, but provide little benefit during extended dry periods. On the other hand, dry period supply operations allow for carrying water in storage through extended dry periods, at a very high cost in average annual yield. This is illustrated by comparing the curves representing Existing Banks Pumping Plant Capacity -- Dry Period Supply Operation in Figures SA-1 and SA-2. As shown in Figure SA-1, at a storage volume of 1.5 maf the Existing Banks Pumping Plant Capacity -- Dry Period Supply Operation reaches an net increase of about 50 taf in 71-Year Average Annual Agricultural and Urban Water Supply Benefits. Figure SA-2 shows that Minimum Annual Agricultural and Urban Water Supply Benefits reach a net benefit of about 250 taf at this same 1.5 maf capacity. However, with the same 1.5 maf storage capacity, the Existing Banks Pumping Plant Capacity -- Normal Period Supply Operation yields about 70 taf net increase for the 71-Year Average Annual Agricultural and Urban Water Supply Benefits compared to 0 taf net increase for the Minimum Annual Agricultural and Urban Water Supply Benefits.

This initial evaluation indicates that with existing Banks Pumping Plant capacity only minor agricultural and urban water supply benefits might be derived from new south of Delta storage facilities. The net increase in 71-Year Average Annual Agricultural and Urban Water Supply Benefits with a 1.5 maf maximum storage capacity is 70 taf. Only minor increases in 71-Year Average Annual Agricultural and Urban Water Supply Benefits are possible with larger maximum storage capacities. Potential net increase in Minimum Annual Agricultural and Urban Water Supply Benefits is about 250 taf and is achieved with this same maximum storage capacity of 1.5 maf.

More significant agricultural and urban water supply benefits might be derived from new south of Delta storage facilities with an expanded Banks Pumping Plant capacity. A net increase in 71-Year Average Annual Agricultural and Urban Water Supply Benefits of about 290 taf is possible with a storage capacity of 2.0 maf. Minor additional 71-Year Average Annual Delta Outflow could be achieved with additional storage capacity, with a net benefit of 310 taf with a 3.0 maf storage capacity. Potential net benefit in Minimum Annual Agricultural and Urban Water Supply Benefits could exceed 420 taf with a maximum storage capacity of 2.0 maf.

Agricultural and Urban Water Supply Benefits versus Storage Carryover Factor Background

The storage carryover factor is an operational parameter designed to provide a means of reserving water supplies for use throughout extended dry periods. In practice, complex reservoir storage carryover rules may be devised to take into account runoff forecasting, variable demand, current storage volume, and other criteria. In this model, a simple storage carryover function has been included which allows the user to set a fraction of end-of-September storage from the previous water year that will be required to remain in storage at the end of the current water year. For example, if 100 taf are in storage at the end of September of the current year, with a storage carryover factor of 70 percent, the storage facility must maintain at least 70 taf by the end of September of the following year. While implementing conservative carryover rules in reservoir operations will increase available supplies during dry periods, total deliveries over normal hydrologic periods will be reduced in comparison to more aggressive reservoir operations.

Model Runs

Storage carryover factors ranging from 0 to 70 percent were varied in a set of model runs to evaluate effects on water supply benefits 1) with and without expanded Banks Pumping Plant capacity and 2) with varied unmet demand targets. These model runs are described in Table SA-3 and summary results are displayed in Table SA-4. For comparability, all results are measured using total south of Delta SWP and CVP water supply deliveries.

Evaluation -- Sensitivity Analysis

Varying the storage carryover factor results in negligible effects for all runs with existing Banks Pumping Plant capacity. Less than 1-percent differences are seen in 71-Year Average Annual Agricultural and Urban Water Supply Benefits and less than 3-percent differences are seen in Minimum Annual Agricultural and Urban Water Supply Benefits throughout the range of storage carryover factors evaluated. Charts displaying the five measures of Agricultural and Urban Water Supply Benefits described in Table SA-2 are plotted versus storage carryover factor for the existing Banks Pumping Plant capacity condition are shown in Figures SA-3 and SA-4.

More substantial effects occur in runs with expanded Banks Pumping Plant capacity. While less than 1-percent decreases in 71-Year Average Annual Agricultural and Urban Water Supply Benefits occur while varying storage carryover factors between 0 percent and 70 percent, Minimum Annual Agricultural and Urban Water Supply Benefits increase up to 11 percent. Plots of the five measures of Agricultural and Urban Water Supply Benefits versus storage carryover factor for the expanded Banks Pumping Plant capacity condition are shown in Figures SA-5 and SA-6.

The storage carryover factor has a minor effect in reserving water supplies through extended dry periods, but corresponding losses in normal period supply are negligible. The storage carryover factor has a larger relative effect with larger unmet target demands. Storage carryover factors of 50 to 60 percent appear to be the most effective.

Water Supply Benefits versus Unmet Demand Target

Background

Unmet south of Delta SWP and CVP demands are used in this evaluation as a surrogate for agricultural and urban water demands. Higher demand levels deplete reservoir storage more often, resulting in higher average deliveries over normal hydrologic periods but reduced deliveries during extended dry periods.

Model Runs

Unmet demand targets ranging from SWP-only unmet demand to combined SWP and CVP unmet demand were varied in a set of model runs to evaluate effects on water supply benefits 1) with and without expanded Banks Pumping Plant capacity and 2) varied storage carryover factors. These model runs are described in Table SA-5 and summary results are displayed in Table SA-6. For comparability, all results are measured using total south of Delta SWP and CVP water supply deliveries.

Evaluation-- Sensitivity Analysis

Moderate effects of varying unmet demand targets are observed in runs with existing Banks Pumping Plant capacity. Less than a 1-percent increase in 71-Year Average Annual Agricultural and Urban Water Supply Benefits is observed while up to 13-percent decreases occur in Minimum Annual Agricultural and Urban Water Supply Benefits as the unmet demand target is increased from unmet SWP demand to combined unmet SWP and CVP demand. Minor effects are seen in dry and critical year averages, all within a 4-percent range. Bar charts of the five measures of Agricultural and Urban Water Supply Benefits for various unmet demand targets for the existing Banks Pumping Plant capacity condition are shown in Figures SA-7 through SA-10.

Moderate effects are also observed in runs with expanded Banks Pumping Plant capacity. Increases of up to 2 percent occur in 71-Year Averages Annual Agricultural and Urban Water Supply Benefits. Increases of up to 17 percent in Minimum Annual Agricultural and Urban Water Supply Benefits result as the operating target is reduced from SWP and CVP unmet demand to SWP-only unmet demand. with storage carryover factor set at 0 percent. Plots of the five measures of Agricultural and Urban Water Supply Benefits versus unmet demand target for the expanded Banks Pumping Plant condition are shown in Figures SA-11 through SA-14.

This operational parameter has a significant effect on Minimum Annual Agricultural and Urban Water Supply Benefits, particularly with expanded Banks Pumping Plant capacity in place. Corresponding effects on 71-Year Average Annual Agricultural and Urban Water Supply Benefits are minor. The largest effects occur with storage carryover factor set at 0 percent.

Selection of Bracketing Operational Parameter Sets

As described in the previous sections, sensitivity analyses were conducted using the CALFED spreadsheet operations model to identify the effects of various operational parameters on environmental water supply benefits. Using the information developed through this process, parameter sets were selected to represent the four bracketing operation conditions described in Table SA-1.

Parameter sets which maximized 71-Year Average Annual Agricultural and Urban Water Supply Benefits were chosen for the Normal Period Supply Operation conditions. Emphasizing this long-term average clearly results in the largest quantity of total water supply deliveries over normal hydrologic periods. Developing a rational for selecting parameter sets for Dry Period Supply Operation conditions is more complex. In general, the sensitivity analyses described above show that more aggressive storage operations (lower storage carryover requirements, higher unmet demand targets) result in larger Average Dry Year, Average Critically Dry Year, or 1928-34 Critical Dry Period Average Annual Agricultural and Urban Water Supply Benefits. When examined in detail, however, it was found the large averages are often due to a particularly large storage release in one or two years, while no benefits are provided during many other critical years. Minimum Annual Agricultural and Urban Water Supply Benefits were maximized with more conservative operating criteria (higher storage carryover requirements and lower unmet demand targets); however, maximizing minimum annual deliveries may not be a cost-effective operational goal for agricultural and urban water supply benefits. To provide a reasonable bracketing operation condition, it was decided to use a 50 percent storage carryover factor and SWPonly unmet demand target for Dry Period Supply Operations. This set of operation parameters provides a more uniform distribution of water supply benefits in dry and critically dry years, with minimal impacts to normal period average benefits.

Parameter sets for Normal Period Supply Operation and Dry Period Supply Operation were identified for the two external conditions considered in this evaluation, existing Banks Pumping Plant capacity and expanded Banks Pumping Plant capacity. The resulting parameter sets for each of the four bracketing operation conditions are detailed in Table SA-7.

Table SA-7

D. Expanded Banks PP Capacity Dry Period Supply Operation	SDI Banks PP Capacity Storage Carryover Factor = 50% Unmet Demand Target = SWP

Comparison of Bracketing Operation Conditions

Model Runs

Model runs were completed for each of the four operation conditions using the parameter sets described in Table SA-7. For comparative purposes, maximum storage volume was set at 2.0 maf with a 3,500 cfs inflow/outflow capacity. Table SA-8 compares the total and net increased Agricultural and Urban Water Supply Benefits under each operation condition.

Evaluation

The Normal Period Supply and Dry period Supply Operation conditions bracket the range of potential storage operations. Normal Period Supply Operation maximizes total average water supply benefits, as measured by the 71-Year Average Annual Agricultural and Urban Water Supply Benefits. Dry Period Supply Operation maximizes water supply benefits in extremely dry years, as measured by the Minimum Annual Agricultural and Urban Water Supply Benefits. Contrasting these bracketing operations for the existing Banks Pumping Plant capacity condition, Normal Period Supply Operation (Condition A) results in a net benefit of 75 taf in 71-Year Average Annual Agricultural and Urban Water Supply Benefits, as compared to a net benefit of 52 taf under Dry Period Supply Operation (Condition B). Conversely, Dry Period Supply Operation (Condition B) results in a net benefit of 250 taf in Minimum Annual Agricultural and Urban Water Supply Benefits, compared to a net benefit of 0 taf in Minimum Annual Agricultural and Urban Water Supply Benefits under Normal Period Supply Operation (Condition A).

More significant benefits are achieved under the expanded Banks Pumping Plant capacity conditions. Contrasting the bracketing Operation Conditions C and D, Normal period Supply Operation (Condition C) results in a net benefit of 286 taf in 71-Year Average Annual Agricultural and Urban Water Supply Benefits, as compared to a net benefit of 52 taf under Dry Period Supply Operation (Condition D). Conversely, Dry Period Supply Operation (Condition D) results in a net benefit of 423 taf in Minimum Annual Agricultural and Urban Water Supply Benefits, compared to a net benefit of 0 taf in Minimum Annual Agricultural and Urban Water Supply Benefits under Normal Period Supply Operation (Condition C).

Figures SA-15 and SA-16 compare the relative effects of the four operation conditions on an annual basis. In these charts, bars represent the total Agricultural and Urban Water Supply Benefits for the 71 years used in the model simulations, sorted from minimum to maximum. For comparison, base case Agricultural and Urban Water Supply Benefits is represented with a line in each chart. Figure SA-15 compares Normal Period Supply and Dry Period Supply Operations for the existing Banks Pumping Plant capacity condition. While minor benefits are seen during drier years under Dry Period Supply Operation (Condition B), benefits during average and above-average water years are significantly reduced. Similarly, Figure SA-16 compares Normal Period Supply and Dry Period Supply Operations for the expanded Banks Pumping Plant capacity condition. More significant benefits occur during the very driest years under Dry Period Supply Operation (Condition D); however, benefits during average-type water years are once again significantly reduced in comparison to Normal Period Supply Operation.

Figure SA-17 presents the same data used in Figures SA-15 and SA-16 in a frequency-of-exceedence format. In this chart, total annual Agricultural and Urban Water Supply Benefits

for the base case and the four operation conditions are plotted against frequency of exceedence. As described above, significantly higher benefits in average-type years are shown with Normal Period Supply Operation, with relatively smaller net gains in drier years under Dry Period Supply Operation.

To provide a better understanding of the year-to-year operations that occur under the four bracketing operation conditions, Figures SA-18 through SA-21 display the simulated storage releases that occur throughout the 71-year hydrological sequence. In each chart, bars represent annual volumes of storage releases and a solid line represents the annual volume of water required to fully meet the combined SWP and CVP unmet demand targets. In Dry Period Supply Operations, the SWP-only unmet demand target was used to control storage operations. A dashed line represents the annual volume of water required to meet this operational target. As can be seen in these charts, under Normal Period Supply Operations (Conditions A and C) larger annual volumes of water are released in relatively few years of the 71-year hydrologic sequence. Under Dry Period Supply Operations (Conditions B and D), annual releases are much smaller, but occur on a much more frequent basis.

Simulated end-of-month storage volumes for the four bracketing operation conditions are shown in Figures SA-22 through SA-25. As expected, storage volumes show sharper draw downs and larger variability under Normal Period Supply Operations (Conditions A and C) in comparison to Dry Period Supply Operations (Conditions B and D). Under Conditions A and B (Existing Banks Pumping Plant), the maximum storage volume of 2.0 maf is reached in only one year of the 71-year hydrologic sequence. Contrarily, under Condition D (Expanded Banks Pumping Plant Capacity -- Dry Period Supply Operation), the 2.0 maf storage volume fills in 17 years of the 71-year hydrologic sequence.

Water Supply Benefits versus Maximum Storage Volume

Maximum storage volumes ranging from 100 taf to 2.0 maf were varied in a set of model runs that simulated the four bracketing operation conditions described previously. These model runs are described in Table SA-9 and summary results are displayed in Tables SA-10 and SA-11. For comparability, all results are measured using total south of Delta SWP and CVP water supply deliveries.

Evaluation

Table SA-10 displays the five statistical measures of total Agricultural and Urban Water Supply Benefits achieved over the range of maximum storage volumes studied for each of the bracketing operation conditions. Table SA-11 displays net increases in Agricultural and Urban Water Supply Benefits for the same range of maximum storage volumes and operation conditions. Figures SA-26 through SA-30 display plots of total Agricultural and Urban Water Supply Benefits versus maximum storage volumes. Figures SA-31 and SA-35 display plots of net increases in Agricultural and Urban Water Supply Benefits. The wide range of benefits seen in these plots between operation conditions for any given maximum reservoir volume confirms that operation conditions must be more thoroughly defined before the maximum storage volume of south of Delta storage facilities can be optimized.

Figures SA-26 and SA-31 show that maximum 71-Year Average Annual Agricultural and Urban Water Supply Benefits are achieved under Condition C (Expanded Banks Pumping Plant Capacity -- Normal Period Supply Operation). Under this operating condition, 71-Year Average Annual Agricultural and Urban Water Supply Benefits continues to increase with diminishing incremental benefit throughout the range of maximum storage volumes evaluated. With a maximum storage volume of 3.0 maf, the largest maximum storage volume evaluated, a net increase of 308 taf is observed in 71-Year Average Annual Agricultural and Urban Water Supply Benefits. About 75 percent of this net benefit, a 232 taf increase in 71-Year Average Annual Agricultural and Urban Water Supply Benefits, is achieved with a maximum storage volume of only 1.0 maf.

Under Condition A (Existing Banks Pumping Plant Capacity -- Normal Period Supply Operation), 71-Year Average Annual Agricultural and Urban Water Supply Benefits increases through about 2.0 maf maximum storage capacity, but with smaller incremental gains in comparison to Condition C. Net 71-Year Average Annual Agricultural and Urban Water Supply Benefits remain constant between 2.0 and 3.0 maf maximum storage capacity. With a maximum storage volume of 2.0 maf, a net increase of 75 taf occurs in 71-Year Average Annual Agricultural and Urban Water Supply Benefits. About 79 percent of this net benefit, or 59 taf is achieved with a 500 taf maximum storage volume.

Figures SA-30 and SA-35 indicate that the largest Minimum Annual Agricultural and Urban Water Supply Benefits is achieved under Condition D (Expanded Banks Pumping Plant Capacity -- Dry Period Supply Operation). Under this operating condition, Minimum Annual Agricultural and Urban Water Supply Benefits increases dramatically between maximum storage volumes of 0 and 1.5 maf. Additional net benefits with decreased incremental gains between 1.5 and 3.0 maf. A maximum net benefit of 479 taf in Minimum Annual Agricultural and Urban Water Supply Benefits is observed with a maximum storage volume of 3.0 maf.

About 83 percent of this net benefit, or 397 taf is achieved with a 1.5 maf maximum storage volume.

Under Condition B (Existing Banks Pumping Plant Capacity -- Dry Period Supply Operation), a net increase in Minimum Annual Agricultural and Urban Water Supply Benefits of 228 taf is observed with a maximum storage volume of 1.5 maf. Under Condition B, no significant additional agricultural and urban water supply benefits are achieved with maximum storage volumes larger than 1.5 maf.
